# 1 The setting

We briefly introduce the object we are about to study. Basic definitions are taken from [3]

In a similar way we define cochain complexes in usual topological cohomology we can define in the same way cochain complexes in group cohomology

**Definition** (Cochain complex). *Given a discrete group  $\Gamma$  and an abelian group  $A$ , the cochain complex is defined as*

$$C^n(\Gamma, A) = \{f : \Gamma^{n+1} \rightarrow A\}, \quad C_b^n(\Gamma, A) = \{f : \Gamma^{n+1} \rightarrow A \mid f \text{ is bounded}\}$$

What makes a function bounded is the existence of a constant  $C$  such that  $f(\gamma_0, \dots, \gamma_n) < C \forall \gamma_i \in \Gamma$

**Definition** (Coboundary operator). *This operator "raises" the degree of the cochains  $\delta : C^n(\Gamma, A) \rightarrow C^{n+1}(\Gamma, A)$*

$$\delta f(\gamma_0, \dots, \gamma_{n+1}) = \sum_{i=0}^{n+1} (-1)^i f(\gamma_0, \dots, \hat{\gamma}_i, \dots, \gamma_{n+1})$$

It is straightforward to check  $\delta^{k+1} \circ \delta^k = 0$

However, if we define directly the cohomology from the above cochain complex, the information encoded in the structure of the group will be lost, treating the group like a set. For that reason we introduce the  $\Gamma$ -invariant cochain complex.

**Definition** (Cochain complex of  $\Gamma$ -invariants). *This is the subset of the cochain complex  $C^n(\Gamma, A)^\Gamma \subseteq C^n(\Gamma, A)$  whose elements fulfill*

$$f(\gamma_0, \dots, \gamma_n) = f(\gamma\gamma_0, \dots, \gamma\gamma_n) \quad \forall \gamma \in \Gamma$$

This is what endows the cochains with the required structure to properly study a group. For convenience we will shorten the notation and we will make use of  $\Gamma$ -invariant cochain complex when not specified.

With this in mind we can define now the usual cohomology with the diagram in mind

$$0 \longrightarrow C^0(\Gamma, A) \xrightarrow{\delta^0} C^1(\Gamma, A) \xrightarrow{\delta^1} C^2(\Gamma, A) \xrightarrow{\delta^2} C^3(\Gamma, A) \xrightarrow{\delta^3} \dots$$

**Definition** (Group Cohomology). *We define the group cohomology from the Cochain complex and the coboundary operator as  $H^n(\Gamma, A) = \frac{\ker(\delta^n)}{\text{Im}(\delta^{n-1})}$*

This is well defined in both cases, the bounded and the unbounded. We realize that the fact  $C_b^n(\Gamma, A) \subseteq C^n(\Gamma, A)$  induces a map called comparison map

$$c : H_b^n(\Gamma, A) \rightarrow H^n(\Gamma, A)$$

The study of this comparison map is fundamental to understand how boundedness can change the setting of the problem.

## 2 Inhomogeneous formulation

To make computations in low degree we usually make use of inhomogeneous complex to transform the trivial action condition in something easier to work with.

Values of  $f$  can be calculated on tuples starting with 1.

$$f(\gamma_0, \dots, \gamma_n) = f(1, \gamma_0^{-1}\gamma_1, \gamma_0^{-1}\gamma_2, \dots, \gamma_0^{-1}\gamma_n)$$

and we let

$$\begin{cases} g_1 = \gamma_0^{-1} \gamma_1 \\ g_2 = \gamma_1^{-1} \gamma_2 \\ \vdots \\ g_n = \gamma_{n-1}^{-1} \gamma_n \end{cases} \Rightarrow f(\gamma_0, \dots, \gamma_n) \leftrightarrow f(1, g_1, g_1 g_2, \dots, g_1 g_2 \cdots g_n) := h(g_1, g_2, \dots, g_n)$$

And this defines a correspondence between the homogeneous and inhomogeneous complexes, which we denote by  $\overline{C}^n$ .

It is easy to check that the coboundary operator transforms in the following way

**Definition** (Inhomogeneous coboundary operator).

$$\overline{\delta}^n h(g_1, \dots, g_{n+1}) = h(g_2, \dots, g_{n+1}) + \sum_{i=1}^n (-1)^i h(g_1, \dots, g_i g_{i+1}, \dots, g_{n+1}) + (-1)^{n+1} h(g_1, \dots, g_n)$$

Henceforth we will write  $h(g_1, \dots, g_n)$  when working with inhomogeneous complexes and  $f(\gamma_0, \dots, \gamma_n)$  with homogeneous. We forget the bar notation, since could be derived from the context.

Two classical computation follow, the groups  $H^0$  and  $H^1$ :

**Proposition.** For any discrete group  $H^0(\Gamma, A) = H_b^0(\Gamma, A) = A$

**Proposition.** For any discrete group  $H^1(\Gamma, A) = \text{Hom}(\Gamma, A)$  and  $H_b^1(\Gamma, \mathbb{Z}) = 0$

We might be surprised by the different result that boundedness gives us on the computation of  $H_b^1$ , but this is the consequence of the fact that there are no bounded homomorphisms from  $\Gamma$  to  $\mathbb{Z}$  or  $\mathbb{R}$ .

### 3 Quasimorphisms

Computing  $H_b^2$  is far more complicated than  $H_b^0$  and  $H_b^1$ . There is a classical result that asserts  $H^2$  is in one-to-one correspondence with the isomorphism classes of central extensions of  $\Gamma$  by  $A$ . For the case of bounded cohomology we introduce the idea of quasimorphism.

**Definition** (Quasimorphisms). Let  $\Gamma$  a group. The space of quasimorphisms is defined as follows

$$QM(\Gamma) = \{f : \Gamma \rightarrow \mathbb{R} : \exists C > 0 \text{ such that } |f(g_1) + f(g_2) - f(g_1 g_2)| < C \forall g_1, g_2 \in \Gamma\}$$

The study of the following map is crucial for the understanding of the relationship between quasimorphisms and bounded cohomology of degree 2.

$$QM(\Gamma) \xrightarrow{A} \ker(H_b^2(\Gamma, \mathbb{R}) \xrightarrow{c} H^2(\Gamma, \mathbb{R}))$$

that sends each quasimorphism  $\varphi \in QM(\Gamma)$  to  $[\delta^1 \varphi] \in H_b^2$ . This is trivially well defined, since  $\delta^2 \circ \delta^1 \varphi = 0$ , in such a way that  $\delta^1 \varphi \in \ker(\delta^2)$ , and, thus, is mapped to zero in  $H^2(\Gamma, \mathbb{R})$ . Taking into account the following diagram:

$$\begin{array}{ccccc} C^1 & \xrightarrow{\delta^1} & C^2 & \xrightarrow{\delta^2} & C^3 \\ \uparrow & & \uparrow & & \uparrow \\ C_b^1 & \xrightarrow{\delta_b^1} & C_b^2 & \xrightarrow{\delta_b^1} & C_b^3 \end{array} \Rightarrow \begin{cases} \ker(\delta_b^2) \subseteq \ker(\delta^2) \\ \text{Im}(\delta_b^1) \subseteq \text{Im}(\delta^1) \end{cases}$$

what suggest that there are some coboundaries  $\delta^1 \varphi$  of  $C^1$  which are not coboundaries of  $C_b^1$ . This is the case of unbounded  $\varphi$  that leads to a quasimorphism (there are a few examples later developed such as Brook's or Rolli's quasimorphisms).

Thus, we can decompose every quasimorphism that maps to zero under the map  $A$  as a sum of homomorphism and a bounded function.  $\ker(A) = B(\Gamma, \mathbb{R}) \oplus \text{Hom}(\Gamma, \mathbb{R})$ . By the surjectivity of the map finally we have the isomorphism

$$\ker(A : H_b^2(\Gamma, \mathbb{R}) \rightarrow H^2(\Gamma, \mathbb{R})) \cong \frac{QM(\Gamma)}{\text{Hom}(\Gamma, \mathbb{R}) \oplus B(\Gamma, \mathbb{R})}$$

## 4 The free group

We apply now the techniques of bounded cohomology to the study of the free group. We start with the free group of two elements.

**Definition** (Free group on two elements). *We call  $F_2 = \langle a, b \rangle$  the group of reduced words generated by the alphabet  $\{a, b, a^{-1}, b^{-1}\}$*

Now we recall that  $H^2(F, \mathbb{R}) = 0$ , and the kernel of the comparison map is the whole space  $H_b^2(F, \mathbb{R})$ , giving the isomorphism

$$H_b^2(F, \mathbb{R}) \cong \frac{QM(F)}{\text{Hom}(F, \mathbb{R}) \oplus B(F, \mathbb{R})}$$

What means that we can express every nontrivial element  $[\delta\varphi] \in H_b^2$ , being  $\varphi$  a quasimorphism which is not bounded nor a homomorphism.

The main advantage of working with cohomology instead of homology is that cohomology is endowed with a cup product defined in the following way:

**Definition** (Cup product). *We define the cup product as the map*

$$\begin{aligned} \cup : H^n(G, \mathbb{R}) \times H^m(G, \mathbb{R}) &\rightarrow H^{n+m}(G, \mathbb{R}) \\ ([f], [g]) &\mapsto [f] \cup [g] \end{aligned}$$

where  $(f \cup g)(g_1, \dots, g_n, g_{n+1}, \dots, g_{n+m}) := f(g_1, \dots, g_n) \cdot g(g_{n+1}, \dots, g_{n+m})$

Two main open questions are now natural to ask:

**Open Problem.** *Can we characterise the group  $H_b^2(F, \mathbb{R})$ ?*

**Open Problem.** *Let  $k > 0$  and  $\alpha \in H_b^k(F, \mathbb{R})$  arbitrary. Let  $\varphi$  be a quasimorphism. Is the map*

$$\begin{aligned} \cup : H_b^2(F, \mathbb{R}) \times H_b^k(F, \mathbb{R}) &\rightarrow H_b^{k+2}(F, \mathbb{R}) \\ ([\delta^1\varphi], \alpha) &\mapsto \beta \end{aligned}$$

*trivial? (i.e.  $\beta = [0]$ )*

## 5 Known quasimorphisms

Although Brooks, Rolli and  $\Delta$ -decomposable quasimorphisms are the most well-known quasimorphisms, we can extend the Brooks quasimorphisms by summing them to form Calegari quasimorphisms.

### 5.1 Calegari Quasimorphisms

Calegari Quasimorphisms are a generalization of small Brooks quasimorphisms. This type of quasimorphisms can be thought as a weighted sum of small Brooks quasimorphisms

$$\varphi_\alpha := \sum_{w \in \mathcal{N}^+} \alpha_w h_w$$

where  $\alpha$  is an alternating function  $\alpha : F \rightarrow \mathbb{R}$  and the sum runs for the set of non-self-overlapping words.

**Definition.** Let

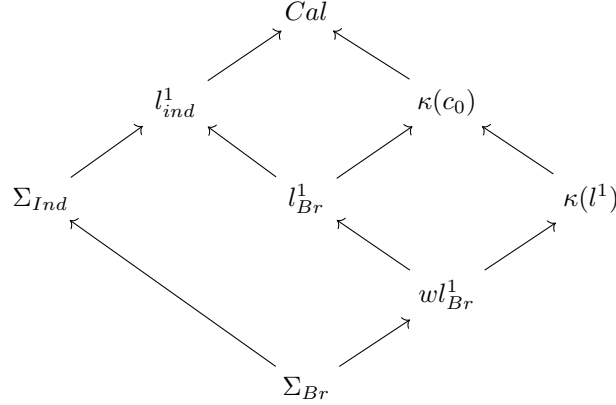

$$\kappa_\alpha(1) := \sup \left( \sum_{w \in C} |\alpha_w| \right)$$

be the supremum over all compatible families. This is an intrinsic characteristic of the function  $\alpha$ .

**Definition** (Calegari Quasimorphisms). We say  $\varphi_\alpha$  is a Calegari quasimorphism if  $\kappa_\alpha(1) < \infty$

## 5.2 Classification of Calegari quasimorphisms

In [2] the following containment map is proven.

**Definition** ( $\Sigma_{Br}$  quasimorphism). We say  $\varphi \in \Sigma_{Br}$  if is a finite sum of finite Brooks quasimorphisms

**Definition** ( $wl^1_{Br}$  quasimorphism). We say  $\varphi \in wl^1_{Br}$  if

$$\sum_{w \in \mathcal{N}^+} |w| |\alpha_w| < \infty$$

We will show that Theorem A (b) made in [1] for brooks quasimorphisms can be extended for  $wl^1_{Br}$  quasimorphisms.

**Theorem.** If  $\varphi_\alpha \in wl^1_{Br}$ , then  $[\delta\varphi_\alpha] \cup \omega = [0]$

*Proof.* We can proof the following statement in the same way Amontova and Bucher did it in Theorem A (b) [1].

Let  $\eta = \sum_{w \in \mathcal{N}^+} \eta_w$ , with  $\eta_w$  defined as:

$$\eta_w(g, h_1, \dots, h_{k-1}) = \sum_{j=1}^{m-l+1} \chi_w(x_j \cdot \dots \cdot x_{j+l-1}) \omega(z_{j+l}(g), h_1, \dots, h_{k-1})$$

where  $z_j(g) = x_j \cdot \dots \cdot x_m$  with  $g = x_1 \cdot \dots \cdot x_m$

Now we let  $\beta = \varphi_\alpha \cup \omega + \delta\eta = \sum_{w \in \mathcal{N}^+} (\alpha_w h_w \cup \omega + \delta\eta_w)$ . One can check that  $\delta\beta = (\delta\varphi_\alpha) \cup \omega$ , and we only need to show that  $\beta$  is bounded.

From the original theorem we know that  $\|\beta_w\| \leq (|w|-1)\|\omega\|_\infty$ , so  $\|\beta_w\| \leq \sum_{w \in \mathcal{N}^+} ((|w|-1)\alpha_w)\|\omega\|_\infty < \infty$ , because  $\varphi_\alpha \in wl^1_{Br}$   $\square$
